Abstract

We prove that the basic intersection cohomology $\boldsymbol{H}^*_{\overline{p}}(M/\mathcal{F})$, where $\mathcal{F}$ is the singular foliation determined by an isometric action of a Lie group G on the compact manifold M, is finite dimensional.

This paper deals with an action $\Phi\colon G\times M\to M$ of a Lie group on a compact manifold preserving a riemannian metric on it. The orbits of this action define a singular foliation $\mathcal{F}$ on M. Putting together the orbits of the same dimension we get a stratification of M. This structure is still very regular. The foliation $\mathcal{F}$ is in fact a conical foliation and we can define the basic intersection cohomology $\boldsymbol{H}^*_{\overline{p}}(M/\mathcal{F})$ (cf. [10]). This invariant becomes the basic cohomology $H^*(M/\mathcal{F})$ when the action Φ is almost free, and the intersection cohomology $\boldsymbol{H}^*_{\overline{p}}(M/G)$ when the Lie group G is compact.

The aim of this work is to prove that this cohomology $\boldsymbol{H}^*_{\overline{p}}(M/\mathcal{F})$ is finite dimensional. This result generalizes [3] (almost free case), [11] (abelian case) and [10] (compact case).

The paper is organized as follows. In Section 1 we present the foliation $\mathcal{F}$. The basic intersection cohomology $\boldsymbol{H}^*_{\overline{p}}(M/\mathcal{F})$ associated to this foliation is studied in Section two. Twisted products are studied in Section 3. The finiteness of $\boldsymbol{H}^*_{\overline{p}}(M/\mathcal{F})$ is proved in Section 4.

In the sequel M is a connected, second countable, Haussdorff, without boundary and smooth (of class C^∞) manifold of dimension m. All the maps are considered smooth unless something else is indicated.

1 Killing foliations determined by isometric actions.

We study in this work the foliations induced by isometric actions: the *Killing foliations*. These foliations are examples of the conical foliations for which the basic intersection cohomology has been defined (see [10, 11]). We present this geometrical framework in this section.

1.1 Killing foliations. A smooth action $\Phi\colon G\times M\to M$ of a Lie group G on a manifold M is a *isometric action* when there exists a riemannian metric μ on M preserved by G.

The connected components of the orbits of the action Φ determine a partition $\mathcal{F}$ on M. In fact, this partition is a singular riemannian foliation that we shall call *Killing foliation* (cf. [7]). Notice that $\mathcal{F}$ is also a conical foliation in the sense of [10, 11]. Classifying the points of M following the dimension of the leaves of $\mathcal{F}$ one gets the *stratification* $\mathsf{S}_{\mathcal{F}}$ of $\mathcal{F}$. It is determined by the equivalence relation $x\sim y\Leftrightarrow \dim G_x=\dim G_y$. The elements of $\mathsf{S}_{\mathcal{F}}$ are called *strata*.

In the particular case where the closure of G in the isometry group of (M,μ) is a compact Lie group[1] we shall say that the action Φ is a *tame action*. In fact, a smooth action $\Phi\colon G\times M\to M$ is tame if and only if it extends to a smooth action $\Phi\colon K\times M\to M$ where K is a compact Lie group containing G (cf. [6]). The group K is not unique, but we always can choose K in such a way that G is dense in K. We shall say that K is a *tamer group*. Here the strata of $\mathsf{S}_{\mathcal{F}}$ are K-invariant closed submanifolds of M.

Since the aim of this work is the study of $\mathcal{F}$ and not the action Φ itself, we can consider that the Lie group G is connected. Let us see that.

Proposition 1.1.1 *Let $\Phi\colon G\times M\to M$ is a tame action. Let G_0 be the connected component of G containing the unity element. The Killing folation defined by the restriction $\Phi\colon G_0\times M\to M$ is also $\mathcal{F}$.*

Proof. The partition $\mathcal{F}$ is defined by this equivalence relation:

$$x\sim y\Longleftrightarrow \exists \text{ continuous path } \alpha\colon[0,1]\to G(x) \text{ such that } \alpha(0)=x \text{ and } \alpha(1)=y.$$

Since the map $\Delta\colon G\to G(x)$, defined by $\Delta(g)=\Phi(g,x)=g\cdot x$, is a submersion (see for example [2]) then

$$x\sim y\Longleftrightarrow \exists \text{ continuous path } \beta\colon[0,1]\to G \text{ such that } \beta(0)=e \text{ and } \beta(1)\cdot x=y,$$

and by definition of G_0

$$x\sim y\Longleftrightarrow \exists \text{ continuous path } \beta\colon[0,1]\to G_0 \text{ such that } \beta(0)=e \text{ and } \beta(1)\cdot x=y.$$

This gives the result. ♣

When G is connected, the tamer group K has richer properties.

Proposition 1.1.2 *Let G be a connected Lie subgroup of a compact Lie group K. If G is dense in K then $G\triangleleft K$ and the quotient group K/G is commutative.*

Proof. The Lie algebra $\mathfrak{g}$ is Ad_G- invariant and hence, by density, Ad_K-invariant. Then $\mathfrak{g}$ is an ideal of $\mathfrak{k}$. The connectedness of G gives that G is a normal subgroup of K. Since Ad_G acts trivially on $\mathfrak{k}/\mathfrak{g}$, Ad_K acts trivially, too. Therefore, $\mathfrak{k}/\mathfrak{g}$ is abelian (see for example [8, pag. 628]). ♣

1.2 Particular tame actions. A *trio* is a triple (K,G,H), with K is a compact Lie group, G a normal subgroup of K and H a closed subgroup of K. We present now some tame actions associated to a trio (K,G,H). They are going to be intensively used in this work. First of all we need some definitions.

- The action $\Phi_l\colon K\times K\to K$ is defined by $\Phi_l(g,k)=g\cdot k$. For each element u of the Lie algebra $\mathfrak{k}$ of K, we shall write X^u the associated (right invariant) vector field. It is defined by $X^u(k)=T_eR_k(u)$ where $R_k\colon K\to K$ is given by $R_k(\ell)=\ell\cdot k$.

[1] This is always the case when the manifold M is a compact.

- The action $\Phi_r\colon K\times K\to K$ is defined by $\Phi_r(g,k)=k\cdot g^{-1}$. For each element $u\in\mathfrak{k}$ of K, we shall write X_u the associated (left invariant) vector field. It is defined by $X_u(k)=-T_eL_k(u)$ where $L_k\colon K\to K$ is given by $L_k(\ell)=k\cdot\ell$.

- The action $\Psi\colon K\times K/H\to K/H$ is defined by $\Psi(g,kH)=(g\cdot k)H$. For each element $u\in\mathfrak{k}$, we shall write Y_u the associated vector field. Since the canonical projection $\pi\colon K\to K/H$ is a K-equivariant map, then we have $\pi_*X^u=Y_u$ for each $u\in\mathfrak{k}$.

- The action $\Gamma\colon H\times H\to H$ is defined by $\Gamma(g,h)=g\cdot h$. For each element u of the Lie algebra $\mathfrak{h}$ of H we write Z^u the associated (right invariant) vector field.

The associated actions we are going to use are the following.

(a) *The restriction $\Phi_l\colon G\times K\to K$, which induces the regular Killing foliation $\mathcal{K}$.*

(b) *The restriction $\Phi_r\colon G\times K\to K$, which induces the regular Killing foliation $\mathcal{K}$.*

Since $G\triangleleft K$, the foliation $\mathcal{K}$ is determined by the family of vector fields $\{X^u\ /\ u\in\mathfrak{g}\}$, where $\mathfrak{g}$ is the Lie algebra of G, and also by the family $\{X_u\ /\ u\in\mathfrak{g}\}$. The orbits $G(k)=Gk=kG$ have the same dimension $\dim G$.

(c) *The restriction $\Psi\colon G\times K/H\to K/H$, which induces the regular Killing foliation $\mathcal{D}$.*

The foliation $\mathcal{D}$ is determined by the family of vector fields $\{Y_u\ /\ u\in\mathfrak{g}\}$. The orbits $G(kH)$ have the same dimension $\dim G-\dim(G\cap H)$.

(d) *The restriction $\Gamma\colon (G\cap H)\times H\to H$, which induces the regular Killing foliation $\mathcal{C}$.*

The foliation $\mathcal{C}$ is determined by the family of vector fields $\{Z^u\ /\ u\in\mathfrak{g}\cap\mathfrak{h}\}$. The orbits $(G\cap H)(k)$ have the same dimension $\dim(G\cap H)$.

(e) *The restriction $\Phi_r\colon GH\times K\to K$, which induces the regular Killing foliation $\mathcal{E}$.*

Notice that GH is a Lie group since G is normal in K. The foliation $\mathcal{E}$ is, in fact, determined by the vector fields $\{X_u\ /\ u\in\mathfrak{g}+\mathfrak{h}\}$. The orbits $(GH)(k)$ have the same dimension $\dim G+\dim H-\dim(G\cap H)$.

1.3 Twisted product. In order to prove the finiteness of the basic intersection cohomology we decompose the manifold in a finite number of simpler pieces. These are the twisted products we introduce now.

We fix a trio (K,G,H) and a smooth action $\Theta\colon H\times N\to N$ of H on the manifold N. The *twisted product* is the quotient $K\times_H N$ of $K\times N$ by the equivalence relation $(k,z)\sim(k\cdot h^{-1},\Theta(h,z)=h\cdot z)$. The element of $K\times_H N$ corresponding to $(k,z)\in K\times N$ is denoted by $<k,z>$. This manifold is endowed with the tame action

$$\Phi\colon G\times(K\times_H N)\longrightarrow(K\times_H N),$$

defined by $\Phi(g,<k,z>)=<g\cdot k,z>$. We denote by $\mathcal{W}$ the induced Killing foliation.

We also use the following tame action, namely, the restriction

$$\Theta\colon (G\cap H)\times N\to N$$

whose induced Killing foliation is denoted by $\mathcal{N}$.

The canonical projection $\Pi\colon K\times N\to K\times_H N$ relates the involved foliations as follows:

(a) $\Pi_*(\mathcal{K}\times\mathcal{I})=\mathcal{W}$, where $\mathcal{I}$ is the pointwise foliation (since the map Π is G-equivariant).

(b) $\mathsf{S}_{\mathcal{W}}=\{\Pi(K\times S)\ /\ S\in\mathsf{S}_{\mathcal{N}}\}=\Pi\left(\{K\}\times\mathsf{S}_{\mathcal{N}}\right)$ (since $G_{<k,z>}=k(G\cap H)_zk^{-1}$).

2 Basic Intersection cohomology

In this section we recall the definition of the basic intersection[2] cohomology and we present the main properties we are going to use in this work. For the rest of this section, we fix a conical foliation $\mathcal{F}$ defied on a manifold M. The associated stratification is $\mathsf{S}_{\mathcal{F}}$. The regular stratum of is denoted by $R_{\mathcal{F}}$. We shall write $m = \dim M$, $r = \dim \mathcal{F}$ and $s = m - r = \operatorname{codim}_M \mathcal{F}$.

We are going to deal with differential forms on a product (manifold) $\times [0,1[^p$, they are restrictions of differential forms defined on (manifold)$\times]-1,1[^p$.

2.1 Perverse forms. Recall that a *conical chart* is a foliated diffeomorphism $\varphi\colon (\mathbb{R}^{m-n-1} \times c\mathbb{S}^n, \mathcal{H} \times c\mathcal{G}) \to (U, \mathcal{F}_U)$ where $(\mathbb{R}^{m-n-1}, \mathcal{H})$ is a simple foliation and $(\mathbb{S}^n, \mathcal{G})$ is a conical foliation without 0-dimensional leaves. We also shall denote this chart by (U, φ, S) where S is the stratum of $\mathsf{S}_{\mathcal{F}}$ verifying $\varphi(\mathbb{R}^{m-n-1} \times \{\vartheta\}) = U \cap S$.

The differential complex $\Pi^*_{\mathcal{F}}(M \times [0,1[^p)$ of *perverse forms* of $M \times [0,1[^p$ is introduced by induction on depth $\mathsf{S}_{\mathcal{F}}$. When this depth is 0 then

$$\Pi^*_{\mathcal{F}}(M \times [0,1[^p) = \Omega^*(M \times [0,1[^p).$$

Consider now the generic case. A perverse form of $M \times [0,1[^p$ is first of all a differential form $\omega \in \Omega^*(R_{\mathcal{F}} \times [0,1[^p)$ such that,

$$\begin{cases} \text{the pull-back} & (\varphi \times \mathbb{I}_{[0,1[^p})^*\omega \in \Omega^*\left(\mathbb{R}^{m-n-1} \times R_{\mathcal{G}} \times]0,1[\times [0,1[^p\right) \\ \text{extends to} & \omega_\varphi \in \Pi^*_{\mathcal{H}\times c\mathcal{G}}\left(\mathbb{R}^{m-n-1} \times \mathbb{S}^n \times [0,1[^{p+1}\right) \end{cases}$$

for any conical chart (U, φ), where $\mathbb{I}_\bullet$ stands for the identity map. Notice that $\Omega^*(M)$ is included on $\Pi^*_{\mathcal{F}}(M)$[3].

2.2 Perverse degree. The amount of transversality of a perverse form $\omega \in \Pi^*_{\mathcal{F}}(M)$ with respect to a singular stratum $S \in \mathsf{S}_{\mathcal{F}}$ is measured by the perverse degree $\|\omega\|_S$. We recall here the definition of local perverse degree $\|\omega\|_U \in \{-\infty\} \cup \mathbb{N}$ of ω relatively to a conical chart (U, φ, S):

1. $\|\omega\|_U = -\infty$ when $\omega_\varphi \equiv 0$ on $\mathbb{R}^{m-n-1} \times R_{\mathcal{G}} \times \{0\}$,
2. $\|\omega\|_U \leq p$, with $p \in \mathbb{N}$, when $\omega_\varphi(v_0, \ldots, v_p, -) \equiv 0$ where the vectors $\{v_0, \ldots, v_p\}$ are tangent to the fibers of $P_\varphi\colon \mathbb{R}^{m-n-1} \times R_{\mathcal{G}} \times \{0\} \longrightarrow U \cap S$[4].

This number does not depend on the choice of the conical chart (cf. [11, Proposition 1.3.1]). Finally, we define the *perverse degree* $\|\omega\|_S$ by

$$\|\omega\|_S = \sup\left\{\|\omega\|_U \ / \ (U, \varphi, S) \text{ conical chart}\right\}.$$

The perverse degree of $\omega \in \Omega^*(M)$ verifies $\|\omega\|_S \leq 0$ for any singular stratum $S \in \mathsf{S}_{\mathcal{F}}$ (cf. 2.1).

[2] We refer the reader to [10],[11] for details.

[3] Through the restriction $\omega \mapsto \omega_{R_{\mathcal{F}}}$.

[4] The map $P_\varphi\colon \mathbb{R}^{m-n-1} \times \mathbb{S}^n \times [0,1[\longrightarrow U$ is defined by $P_\varphi(x, y, t) = \varphi(x, [y, t])$.

2.3 Basic cohomology. The basic cohomology of the foliation $\mathcal{F}$ is an important tool to study its transversal structure and plays the rôle of the cohomology of the orbit space $M/\mathcal{F}$, which can be a wild topological espace. A differential form $\omega \in \Omega^*(M)$ is *basic* if $i_X\omega = i_X d\omega = 0$, for each vector field X on M tangent to the foliation $\mathcal{F}$. For exemple, a function f is basic iff f is constant on the leaves of $\mathcal{F}$. We shall write $\Omega^*(M/\mathcal{F})$ for the complex of basic forms. Its cohomology $H^*(M/\mathcal{F})$ is the *basic cohomology* of $(M,\mathcal{F})$. We also use the *relative basic cohomology* $H^*((M,F)/\mathcal{F})$, that is, the cohomology computed from the complex of basic forms vanishing on the saturated set $F \subset M$. The basic cohomology does not use the stratification $\mathsf{S}_{\mathcal{F}}$.

2.4 Basic intersection cohomology. A *perversity* is a map $\overline{p}\colon \mathsf{S}^{\sigma}_{\mathcal{F}} \to \mathbb{Z} \cup \{-\infty, \infty\}$, where $\mathsf{S}^{\sigma}_{\mathcal{F}}$ is the family of singular strata. The *constant perversity* $\overline{\iota}$ is defined by $\overline{\iota}(S) = \iota$, where $\iota \in \mathbb{Z} \cup \{-\infty, \infty\}$.

The basic intersection cohomology appears when one considers basic perverse forms whose perverse degree is controlled by a perversity. We shall put

$$\Omega^*_{\overline{p}}(M/\mathcal{F}) = \left\{\omega \in \Pi^*_{\mathcal{F}}(M) \;/\; \omega \text{ is basic and } \max\left(\|\omega\|_S, \|d\omega\|_S\right) \leq \overline{p}(S) \;\; \forall S \in \mathsf{S}^{\sigma}_{\mathcal{F}}\right\}$$

the complex of basic perverse forms whose perverse degree (and that of the their derivative) is bounded by the perversity $\overline{p}$. The cohomology $\boldsymbol{H}^*_{\overline{p}}(M/\mathcal{F})$ of this complex is the *basic intersection cohomology*[5] of $(M,\mathcal{F})$ relatively to the perversity $\overline{p}$.

Consider a twisted product $K\times_H N$. Perversities on $K\times_H N$ and $K \times N$ are determinate by perversities on N by the formula (cf. 1.3(b)):

$$\overline{p}(K \times S) = \overline{p}(\Pi(K \times S)) = \overline{p}(S). \tag{1}$$

2.5 Mayer-Vietoris. This is the technique we use in order to decompose the manifold in nicer pieces. An open covering $\{U, V\}$ of M by saturated open subsets is a *basic covering*. It possesses a subordinated partition of the unity made up of basic functions defined on M (see [9]). For a such covering we have the Mayer-Vietoris short sequence

$$0 \to \Omega^*_{\overline{p}}(M/\mathcal{F}) \to \Omega^*_{\overline{p}}(U/\mathcal{F}) \oplus \Omega^*_{\overline{p}}(V/\mathcal{F}) \to \Omega^*_{\overline{p}}((U \cap V)/\mathcal{F}) \to 0,$$

where the map are defined by $\omega \mapsto (\omega, \omega)$ and $(\alpha, \beta) \mapsto \alpha - \beta$. The third map is onto since the elements of the partition of the unity are *controlled functions*, id est, elements of $\Omega^0_{\overline{0}}(-)$ (cf. 2.2). Thus, the sequence is exact. This result is not longer true for more general coverings.

We shall use in this work the two following local calculations (see [11, Proposition 3.5.1 and Proposition 3.5.2] for the proofs).

Proposition 2.6 *Let $(\mathbb{R}^k, \mathcal{H})$ be a simple foliation. Consider $\overline{p}$ a perversity on M and define the perversity $\overline{p}$ on $\mathbb{R}^k \times M$ by $\overline{p}(\mathbb{R}^k \times S) = \overline{p}(S)$. The canonical projection* $\mathrm{pr} : \mathbb{R}^k \times M \to M$ *induces the isomorphism*

$$\boldsymbol{H}^*_{\overline{p}}(M/\mathcal{F}) \cong \boldsymbol{H}^*_{\overline{p}}\left(\mathbb{R}^k \times M/\mathcal{H} \times \mathcal{F}\right).$$

Proposition 2.7 *Let $\mathcal{G}$ be a conical foliation without 0-dimensional leaves on the sphere $\mathbb{S}^n$. A perversity $\overline{p}$ on $c\mathbb{S}^n$ gives the perversity $\overline{p}$ on $\mathbb{S}^n$ defined by $\overline{p}(S) = \overline{p}(S\times]0,1[)$. The canonical projection* $\mathrm{pr} : \mathbb{S}^n\times]0,1[\to \mathbb{S}^n$ *induces the isomorphism*

$$\boldsymbol{H}^i_{\overline{p}}(c\mathbb{S}^n/c\mathcal{G}) = \begin{cases} \boldsymbol{H}^i_{\overline{p}}(\mathbb{S}^n/\mathcal{G}) & \text{if } i \leq \overline{p}(\{\vartheta\}) \\ 0 & \text{if } i > \overline{p}(\{\vartheta\}). \end{cases}$$

[5] BIC for short.

In the next section we shall need the following technical Lemma.

Lemma 2.8 *Let $\Phi\colon K\times M\to M$ be a smooth action, where K is a compact Lie group, and let V be a fundamental vector field of this action. Consider a normal subgroup G of K and write $\mathcal{F}$ the associated conical foliation on M. Then, the interior operator $i_V\colon \Omega^*_{\overline{p}}(M/\mathcal{F})\longrightarrow \Omega^{*-1}_{\overline{p}}(M/\mathcal{F})$ is well defined, for any perversity $\overline{p}$.*

Proof. Since the question is a local one, then it suffices to consider where M is a twisted product $K\times_H N$[6]. Notice that the blow up $\Pi\colon K\times N\to K\times_H N$ is a K-equivariant map relatively to the action $\ell\cdot(k,z)=(\ell\cdot k,z)$. This gives $\Pi_*(X^u,0)=V$ for some $u\in\mathfrak{k}$. From Lemma 3.1 we know that it suffices to prove that the operator

$$i_{(X^u,0)}\colon \Omega^*_{\overline{p}}(K\times N/\mathcal{K}\times\mathcal{N})\longrightarrow \Omega^{*-1}_{\overline{p}}(K\times N/\mathcal{K}\times\mathcal{N})$$

is well defined. Since $G\triangleleft K$ then the vector field X^u preserves the foliation $\mathcal{K}$. So, it suffices to prove that the operator

$$i_{(X^u,0)}\colon \Omega^*_{\overline{p}}(K\times N)\longrightarrow \Omega^{*-1}_{\overline{p}}(K\times N)$$

is well defined. This comes from the fact that X^u acts on the K-factor while the perversion conditions are measured on the N-factor (cf. (1)). ♣

3 The BIC of a twisted product

We compute now the BIC of a twisted product $K\times_H N$ (cf. 1.3) for a perversity $\overline{p}$ (cf. (1)).

Lemma 3.1 *The natural projection $\Pi\colon K\times N\to K\times_H N$ induces the differential monomorphism*

$$\Pi^*\colon \Omega^*_{\overline{p}}(K\times_H N/\mathcal{W})\longrightarrow \Omega^*_{\overline{p}}(K\times N/\mathcal{K}\times\mathcal{N}). \tag{2}$$

Moreover, given a differential form ω on $K\times_H R_{\mathcal{W}}$, we have:

$$\Pi^*\omega\in\Omega^*_{\overline{p}}(K\times N/\mathcal{K}\times\mathcal{N})\Longleftrightarrow\omega\in\Omega^*_{\overline{p}}(K\times_H N/\mathcal{W}). \tag{3}$$

Proof. Notice that the injectivity of Π^* comes from the fact that Π is a surjection. For the rest, we proceed in several steps.

(a) *A foliated atlas for $\pi\colon K\to K/H$.*

Since $\pi\colon K\to K/H$ is a H-principal bundle then it possesses an atlas $\mathcal{A}=\left\{\varphi\colon \pi^{-1}(U)\longrightarrow U\times H\right\}$ made up with H-equivariant charts: $\varphi(k\cdot h^{-1})=(\pi(k),h\cdot h_0)$ if $\varphi(k)=(\pi(k),h_0)$. We study the foliation $\varphi_*\mathcal{K}$. This equivariance property gives $\varphi_*X_u=(0,Z^u)$ for each $u\in\mathfrak{g}\cap\mathfrak{h}$. Thus, the trace of the foliation $\varphi_*\mathcal{K}$ on the fibers of the canonical projection $\mathrm{pr}: U\times H\to U$ is $\mathcal{C}$. On the other hand, since the map π is a G-equivariant map then $\pi_*\mathcal{K}=\mathcal{D}$, which gives $\mathrm{pr}_*\varphi_*\mathcal{K}=\mathcal{D}$. We conclude that $\varphi_*\mathcal{K}\subset\mathcal{D}\times\mathcal{C}$. By dimension reasons we get $\varphi_*\mathcal{K}=\mathcal{D}\times\mathcal{C}$. The atlas $\mathcal{A}$ is an H-equivariant foliated atlas of π.

(b) *A foliated atlas for $\Pi\colon K\times N\to K\times_H N$.*

[6] In fact, N is an euclidean space $\mathbb{R}^a$ et Θ is an orthogonal action.

We claim that $\mathcal{A}_{\#} = \left\{\overline{\varphi}\colon \pi^{-1}(U)\times_{H}N \longrightarrow U\times N \;/\; (U,\varphi)\in\mathcal{A}\right\}$ is a foliated atlas of $K\times_{H}N$ where the map $\overline{\varphi}$ is defined by $\overline{\varphi}(<k,z>) = (\pi(k),(\Theta((\varphi^{-1}(\pi(k),e))^{-1}\cdot k,z)))$. This map is a diffeomorphism whose inverse is $\overline{\varphi}^{-1}(u,z) =< \varphi^{-1}(u,e),z >$. It verifies

$$\overline{\varphi}_{*}\mathcal{W} \overset{1.3(a)}{=\!=} \overline{\varphi}_{*}\Pi_{*}(\mathcal{K}\times\mathcal{I}) = \overline{\varphi}_{*}\Pi_{*}(\varphi^{-1}\times\mathbb{I}_{N})_{*}(\mathcal{D}\times C\times\mathcal{I}).$$

A straightforward calculation shows $\overline{\varphi}\circ\Pi\circ(\varphi^{-1}\times\mathbb{I}_{N}) = (\mathbb{I}_{U}\times\Theta)$. Since C is defined by the action Γ then $\Theta_{*}(C\times\mathcal{I}) = \mathcal{N}$. Finally we obtain $\overline{\varphi}_{*}\mathcal{W} = \mathcal{D}\times\mathcal{N}$.

(c) *Last Step*.
Given $\overline{(U,\varphi)}\in\mathcal{A}_{\#}$, we have the commutative diagram

$$\begin{array}{ccc} U\times H\times N & \xrightarrow{\varphi^{-1}\times\mathbb{I}_{N}} & K\times N \\ {\scriptstyle Q}\downarrow & & \downarrow{\scriptstyle \Pi} \\ U\times N & \xrightarrow{\overline{\varphi}^{-1}} & K\times_{H}N \end{array}$$

where $Q(u,h,z) = (u,h^{-1}\cdot z)$, $\Pi^{-1}(\mathrm{Im}\ \overline{\varphi}^{-1}) = \mathrm{Im}\left(\varphi^{-1}\times\mathbb{I}_{N}\right)$ and the rows are foliated imbeddings. Now, since (2) and (3) are local questions then it suffices to prove that

- $Q^{*}\colon \Omega^{*}_{\overline{p}}(U\times N/\mathcal{D}\times\mathcal{N}) \longrightarrow \Omega^{*}_{\overline{p}}(U\times H\times N/\mathcal{D}\times C\times\mathcal{N})$ is well-defined, and
- $Q^{*}\omega\in\Omega^{*}_{\overline{p}}(U\times H\times N/\mathcal{D}\times C\times\mathcal{N}) \Longleftrightarrow \omega\in\Omega^{*}_{\overline{p}}(U\times N/\mathcal{D}\times\mathcal{N})$, for any $\omega\in\Omega^{*}(U\times R_{\mathcal{N}})$.

This comes from the fact that the map

$$\nabla\colon (U\times H\times N,\mathcal{D}\times C\times\mathcal{N}) \longrightarrow (U\times H\times N,\mathcal{D}\times C\times\mathcal{N}),$$

defined by $\nabla(u,h,z) = (u,h,h^{-1}\cdot z))$, is a foliated diffeomorphism[7] and $Q = \mathrm{pr}_{0}\circ\nabla$, with $\mathrm{pr}_{0}\colon U\times H\times N\to U\times N$ canonical projection (cf. Proposition 2.6). ♣

3.2 The Lie algebra $\mathfrak{k}$. We suppose in this paragraph that that G is also dense on K. Choose ν a bi-invariant riemannian metric on K, which exists by compactness. Consider

$$B = \left\{u_1,\dots u_a,u_{a+1},\dots,u_b,u_{b+1},\dots,u_c,u_{c+1},\dots,u_f\right\}$$

an orthonormal basis of the Lie algebra $\mathfrak{k}$ of K with $\{u_1,\dots u_b\}$ basis of the Lie algebra $\mathfrak{g}$ of G and $\{u_{a+1},\dots u_c\}$ basis of the Lie algebra $\mathfrak{h}$ of H. For each indice $1\le i\le f$ we shall write $X_i\equiv X_{u_i}$ and $X^i\equiv X^{u_i}$ (cf. 1.2).

Let $\gamma_i\in\Omega^{1}(K)$ be the dual form of X_i, that is, $\gamma_i = i_{X_i}\nu$. Notice that $\delta_{ij} = \gamma_j(X_i)$. These forms are invariant by the left action of K. Since the flow of X^j is the multiplication on the left by $\exp(tu_j)$ then $L_{X^j}\gamma_i = 0$ for each $1\le j\le f$.

For the differential, we have the formula $d\gamma_l = \sum_{1\le i<j\le f} C^{l}_{ij}\gamma_i\wedge\gamma_j$, where $[X_i,X_j] = \sum_{l=1}^{f} C^{l}_{ij}X_l$, and $1\le i,j,l\le f$. We have several restrictions on these coefficients. Since $G\triangleleft K$ then $\mathfrak{g}$ is an ideal of $\mathfrak{k}$ and therefore we have

$$C^{l}_{ij} = 0 \text{ for } i\le b<l.$$

[7] Since $G\cap H\triangleleft H$.

Since K/G is an abelian group (cf. Proposition 1.1.2) then the induced bracket on $\mathfrak{k}/\mathfrak{g}$ is zero and therefore we have

$$C^l_{ij} = 0 \text{ for } b < i, j, l \leq f.$$

These equations imply that

$$d\gamma_l = 0 \text{ for each } b < l. \tag{4}$$

The $\mathcal{E}$-basic differential forms in $\bigwedge^*(\gamma_1, \ldots, \gamma_f)$ are exactly $\bigwedge^*(\gamma_{c+1}, \ldots, \gamma_f)$ since they are cycles and the family $\{X_1, \ldots, X_c\}$ generates the foliation $\mathcal{E}$. This gives

$$H^*\left(K/\mathcal{E}\right) = \bigwedge^*(\gamma_{c+1}, \ldots, \gamma_f). \tag{5}$$

3.3 Two actions of H/H_0. The Lie group H preserves the foliation $\mathcal{N}$ since the Lie group $G \cap H$ is a normal subgroup of H. Put H_0 the connected component of H containing the unity element. Since it is a connected compact Lie group then a standard argument shows that

$$\left(\boldsymbol{H}^*_{\overline{p}}(N/\mathcal{N})\right)^{H_0} = H^*\left(\left(\Omega^*_{\overline{p}}(N/\mathcal{N})\right)^{H_0}\right) = \boldsymbol{H}^*_{\overline{p}}(N/\mathcal{N}) \tag{6}$$

(cf. [5, Theorem I, Ch. IV, vol. II]). We conclude that the finite group H/H_0 acts naturally on $\boldsymbol{H}^*_{\overline{p}}(N/\mathcal{N})$.

Since H_0 is a connected Lie subgroup of GH then $\left(H^*(K/\mathcal{E})\right)^{H_0} = H^*(K/\mathcal{E})$. We conclude that the finite group H/H_0 acts naturally on $H^*(K/\mathcal{E})$.

Proposition 3.4 *Let (K, G, H) be a trio with G connected and dense in K. Then*

$$\boldsymbol{H}^*_{\overline{p}}(K\times_H N/\mathcal{W}) = \left(H^*(K/\mathcal{E}) \otimes \boldsymbol{H}^*_{\overline{p}}(N/\mathcal{N})\right)^{H/H_0}.$$

Proof. Using the blow up $\Pi\colon K \times N \to K\times_H N$, the computation of $\boldsymbol{H}^*_{\overline{p}}(K\times_H N/\mathcal{W})$ can be done by using the complex Im $\left\{\Pi^*\colon \Omega^*_{\overline{p}}(K\times_H N/\mathcal{F}) \longrightarrow \Omega^*_{\overline{p}}(K \times N/\mathcal{K} \times \mathcal{N})\right\}$ (cf. Lemma 3.1). We study this complex in several steps. We fix $B = \left\{u_1, \ldots, u_f\right\}$ an orthonormal basis of $\mathfrak{k}$ as in 3.2.

$\langle i\rangle$ Description of $\Omega^*(K \times R_{\mathcal{N}})$.

A differential form $\omega \in \Omega^*(K \times R_{\mathcal{N}})$ is of the form

$$\eta + \sum_{1\leq i_1<\cdots<i_\ell\leq f} \gamma_{i_1} \wedge \cdots \wedge \gamma_{i_\ell} \wedge \eta_{i_1,\ldots,i_\ell}, \tag{7}$$

where the forms $\eta, \eta_{i_1,\ldots,i_\ell} \in \Omega^*(K \times R_{\mathcal{N}})$ verify $i_{X_j}\eta = i_{X_j}\eta_{i_1,\ldots,i_\ell} = 0$ for each $1 \leq j \leq f$ and each $1 \leq i_1 < \cdots < i_\ell \leq f$.

$\langle ii\rangle$ Description of $\Pi^*_{\mathcal{K}\times\mathcal{N}}(K \times N)$.

Since the foliation $\mathcal{K}$ is regular then we always can choose a conical chart of the form $(U_1 \times U_2, \varphi_1 \times \varphi_2)$ where (U_1, φ_1) is a foliated chart of $(K, \mathcal{K})$ and (U_2, φ_2) is a conical chart of $(N, \mathcal{N})$. The local blow up of the chart $(U_1 \times U_2, \varphi_1 \times \varphi_2)$ is constructed from the second factor without modifying the first one. So, the differential forms γ_i are always perverse forms and a differential form $\omega \in \Pi^*_{\mathcal{K}\times\mathcal{N}}(K \times N)$ is of the form (7) where $\eta, \eta_{i_1,\ldots,i_\ell} \in \Pi^*_{\mathcal{K}\times\mathcal{N}}(K \times N)$ verify $i_{X_j}\eta = i_{X_j}\eta_{i_1,\ldots,i_\ell} = 0$ for each $1 \leq j \leq f$ and each $1 \leq i_1 < \cdots < i_\ell \leq f$.

⟨*iii*⟩ Description of $\Omega^*(K\times R_{\mathcal{N}}/\mathcal{K}\times\mathcal{N})$.

Take $\omega\in\Omega^*(K\times R_{\mathcal{N}}/\mathcal{K}\times\mathcal{N})$. Since $\mathcal{K}$ is generated by the family $\{X_j\ /\ 1\le j\le b\}$ then $L_{X_j}\omega=0$ for any $1\le j\le b$, or equivalently, $R_g^*\omega=\omega$ for each $g\in G$ since G is connected. By density, $R_k^*\omega=\omega$ for each $k\in K$ and therefore $L_{X_j}\omega=0$ for any $1\le j\le f$ since K is connected. We conclude that $L_{X_j}\eta=L_{X_j}\eta_{i_1,\dots,i_\ell}=0$ for any $1\le j\le f$ and each $1\le i_1<\cdots<i_\ell\le f$. This gives $\omega\in\bigwedge^*(\gamma_1,\dots,\gamma_f)\otimes\Omega^*(R_{\mathcal{N}})$.

The $\mathcal{N}$-basic differential forms of $\Omega^*(R_{\mathcal{N}})$ are exactly $\Omega^*(R_{\mathcal{N}}/\mathcal{N})$. The $\mathcal{K}$-basic differential forms of $\bigwedge^*(\gamma_1,\dots,\gamma_f)$ are exactly $\bigwedge^*(\gamma_{b+1},\dots,\gamma_f)$ (cf. (4)). From these two facts, we get

$$\Omega^*(K\times R_{\mathcal{N}}/\mathcal{K}\times\mathcal{N})=\bigwedge\nolimits^*(\gamma_{b+1},\dots,\gamma_f)\otimes\Omega^*(R_{\mathcal{N}}/\mathcal{N})$$

as differential graduate commutative algebras.

⟨*iv*⟩ Description of $\Omega^*_{\overline{p}}(K\times N/\mathcal{K}\times\mathcal{N})$.

From ⟨*ii*⟩ and ⟨*iii*⟩ it suffices to control the perverse degree of the forms

$$\eta+\sum_{b+1\le i_1<\cdots<i_\ell\le f}\gamma_{i_1}\wedge\cdots\wedge\gamma_{i_\ell}\wedge\eta_{i_1,\dots,i_\ell}\in\bigwedge\nolimits^*(\gamma_{b+1},\dots,\gamma_f)\otimes\Pi^*_{\mathcal{N}}(N).$$

Consider S a stratum of $\mathsf{S}_{\mathcal{N}}$. From $\|\gamma_i\|_{K\times S}=0$ and $\|\eta\|_{K\times S}=\|\eta\|_S$, we get $\|\gamma_{i_1}\wedge\dots\gamma_{i_\ell}\wedge\eta_{i_1,\dots,i_\ell}\|_{K\times S}=\|\eta_{i_1,\dots,i_\ell}\|_S$. We conclude that

$$\Omega^*_{\overline{p}}(K\times N/\mathcal{K}\times\mathcal{N})\cong\bigwedge\nolimits^*(\gamma_{b+1},\dots,\gamma_f)\otimes\Omega^*_{\overline{p}}(N/\mathcal{N})$$

(cf. 1.3(b)).

⟨*v*⟩ Description of $\operatorname{Im}\left\{\Pi^*\colon\Omega^*_{\overline{p}}(K\times_H N/\mathcal{F})\longrightarrow\Omega^*_{\overline{p}}(K\times N/\mathcal{K}\times\mathcal{N})\right\}$.

We denote by $\{W_{a+1},\dots,W_c\}$ the fundamental vector fields of the action $\Theta\colon H\times N\to N$ associated to the basis $\{u_{a+1},\dots,u_c\}$. Consider now the action $\Upsilon\colon H\times(K\times N)\to(K\times N)$ defined by $\Upsilon(h,(k,z))=(k\cdot h^{-1},\Theta(h,z))$. Its fundamental vector fields associated to the basis $\{u_{a+1},\dots,u_c\}$ are $\{(X_{a+1},W_{a+1}),\dots,(X_c,W_c)\}$. Given $h\in H$, we take $\Upsilon_h\colon K\times N\to K\times N$ the map defined by $\Upsilon_h(k,z)=\Upsilon(h,(k,z))$. Then, we have

$$\operatorname{Im}\Pi^*=\left\{\omega\in\bigwedge\nolimits^*(\gamma_{b+1},\dots,\gamma_f)\otimes\Omega^*_{\overline{p}}(N/\mathcal{N})\ \middle|\ \begin{array}{l}\text{(i) } i_{X_i}\omega=-i_{W_i}\omega\text{ if }a<i\le c\}\\ \text{(ii) } L_{X_i}\omega=-L_{W_i}\omega\text{ if }a<i\le c\},\\ \text{(iii) }(\Upsilon_h)^*\omega=\omega\text{ for }h\in H.\end{array}\right\}.$$

Let H_0 be the unity connected component of H. Recall that the subgroup H_0 is normal in H and that the quotient H/H_0 is a finite group. Conditions (ii) gives that ω is H_0-invariant. So, condition (iii) can be replaced by: (iv) $(\Upsilon_h)^*\omega=\omega$ for $h\in H/H_0$. Therefore

$$\operatorname{Im}\Pi^*=\left\{\omega\in\bigwedge\nolimits^*(\gamma_{b+1},\dots,\gamma_f)\otimes\Omega^*_{\overline{p}}(N/\mathcal{N})\ \middle|\ \begin{array}{l}\text{(i) } i_{X_i}\omega=-i_{W_i}\omega\text{ if }a<i\le c\}\\ \text{(ii) } L_{X_i}\omega=-L_{W_i}\omega\text{ if }a<i\le c\}.\end{array}\right\}^{H/H_0}.$$

Since the group H/H_0 is a finite one, we get that the cohomology $H^*(\operatorname{Im}\Pi^*)$ is isomorphic to $\left(H^*(A^\cdot)\right)^{H/H_0}$, where A^* is the differential complex

$$\left\{\omega\in\bigwedge\nolimits^*(\gamma_{b+1},\dots,\gamma_f)\otimes\Omega^*_{\overline{p}}(N/\mathcal{N})\ \middle|\ \begin{array}{l}\text{(i) } i_{X_i}\omega=-i_{W_i}\omega\text{ if }a<i\le c\}\\ \text{(ii) } L_{X_i}\omega=-L_{W_i}\omega\text{ if }a<i\le c\}\end{array}\right\}.$$

So, it remains to compute $H^*(A^\cdot)$. This computation can be simplified by using these three facts:

- $i_{W_i}\omega = L_{W_i}\omega = 0$ for each $a < i \leq b$, since the foliation $\mathcal{N}$ is defined by the action of $G \cap H$.
- $i_{X_i}\gamma_j = \delta_{ij}$ for all i, j (cf. 3.2).
- $d\gamma_j = 0$ for $b < j$ (cf. (4)).

We get that A^* is the differential complex

$$\left\{\omega \in \bigwedge\nolimits^*(\gamma_{b+1},\dots,\gamma_f)\otimes\Omega^*_{\overline{p}}(N/\mathcal{N}) \;\middle|\; \begin{array}{l}\text{(i) } i_{X_i}\omega = -i_{W_i}\omega \text{ if } b<i\leq c\}\\ \text{(ii) } 0 = L_{W_i}\omega \text{ if } b<i\leq c\}\end{array}\right\} =$$

$$\bigwedge\nolimits^*(\gamma_{c+1},\dots,\gamma_f)\otimes\underbrace{\left\{\omega \in \bigwedge\nolimits^*(\gamma_{b+1},\dots,\gamma_c)\otimes\Omega^*_{\overline{p}}(N/\mathcal{N}) \;\middle|\; \begin{array}{l}\text{(i) } i_{X_i}\omega = -i_{W_i}\omega \text{ if } b<i\leq c\}\\ \text{(ii) } 0 = L_{W_i}\omega \text{ if } b<i\leq c\}\end{array}\right\}}_{B^*}.$$

A straightforward computation gives that the canonical writing of a form $\omega \in \bigwedge^*(\gamma_{b+1},\dots,\gamma_c)\otimes\Omega^*_{\overline{p}}(N/\mathcal{N})$ verifying (i) is

$$\omega = \omega_0 + \sum_{b<i_1<\cdots<i_\ell\leq c} (-1)^\ell \gamma_{i_1}\wedge\cdots\wedge\gamma_{i_\ell}\wedge(i_{W_{i_\ell}}\cdots i_{W_{i_1}}\omega_0) \tag{8}$$

for some $\omega_0 \in \Omega^*_{\overline{p}}(N/\mathcal{N})$ (cf. Lemma 2.8).

Consider now $b < i, j \leq c$. Since K/G is an abelian group (cf. Proposition 1.1.2) and H is a Lie group then $[W_i, W_j] = \sum_{l=a+1}^{b} C_{ij}^l W_l$. Then, $i_{[W_i,W_j]}\omega_0 = 0$ since the foliation $\mathcal{N}$ is defined by the action of $G \cap H$. So, the canonical writing of a form $\omega \in B^*$ is (8) for some $\omega_0 \in \left\{\eta \in \Omega^*_{\overline{p}}(N/\mathcal{N}) \,/\, L_{W_i}\eta = 0 \text{ if } b<i\leq c\right\} = \left(\Omega^*_{\overline{p}}(N/\mathcal{N})\right)^{H_0}$.

Then, the operator $\Delta\colon B^* \longrightarrow \left(\Omega^*_{\overline{p}}(N/\mathcal{N})\right)^{H_0}$, defined by $\Delta(\omega) = \omega_0$, is a differential isomorphism. We conclude that the differential complex A^* is isomorphic to $\bigwedge^*(\gamma_{c+1},\dots,\gamma_f)\otimes\left(\Omega^*_{\overline{p}}(N/\mathcal{N})\right)^{H_0}$ and therefore $H^*(A^\cdot) \cong H^*(K/\mathcal{E})\otimes \boldsymbol{H}^*_{\overline{p}}(N/\mathcal{N})$ (cf. (5) and (6)). Since the operator Δ is (H/H_0)-equivariant (cf. 3.3) then we get

$$\boldsymbol{H}^*_{\overline{p}}(K\times_H N/\mathcal{W}) \;=\; H^*(\text{Im }\Pi^*) = \left(H^*(A^\cdot)\right)^{H/H_0} = \left(H^*(K/\mathcal{E})\otimes\boldsymbol{H}^*_{\overline{p}}(N/\mathcal{N})\right)^{H/H_0}.$$

This ends the proof. ♣

3.5 Remarks.

(a) When the Lie group G is commutative then K is also commutative. Differential forms $\gamma_\bullet$ are K-invariants on the left and on the right, so $\left(H^*(K/\mathcal{E})\right)^H = H^*(K/\mathcal{E})$ and therefore

$$\boldsymbol{H}^*_{\overline{p}}(K\times_H N/\mathcal{W}) = H^*(K/\mathcal{E})\otimes\left(\boldsymbol{H}^*_{\overline{p}}(N/\mathcal{N})\right)^{H/H_0} = H^*(K/\mathcal{E})\otimes\left(\boldsymbol{H}^*_{\overline{p}}(N/\mathcal{N})\right)^{H}$$

as it has been proved in [11, Proposition 3.8.4].

(b) Since the foliation $\mathcal{E}$ is a riemannian foliation defined on a compact manifold then we know that the cohomology $H^*(K/\mathcal{E})$ is finite (cf. [4]). So, the finiteness of $\boldsymbol{H}^*_{\overline{p}}(K\times_H N/\mathcal{W})$ depends on the finiteness of $\boldsymbol{H}^*_{\overline{p}}(N/\mathcal{N})$.

4 Finiteness of the BIC

We prove in this section that the BIC of a Killing foliation on a compact manifold is finite dimensional. First of all, we present two geometrical tools we shall use in the proof: the isotropy type stratification and the Molino's blow up.

We fix an isometric action $\Phi\colon G\times M \to M$ on the compact manifold M. We denote by $\mathcal{F}$ the induced Killing foliation. For the study of $\mathcal{F}$ we can suppose that G is connected (see Lemma 1.1.1). We fix K a tamer group. Notice that the group G is normal in K and the quotient K/G is commutative (cf. Proposition 1.1.2).

4.1 Isotropy type stratification. The *isotropy type stratification* $\mathsf{S}_{K,M}$ of M is defined by the equivalence relation[8]:

$$x \sim y \Leftrightarrow K_x \text{ is conjugated to } K_y.$$

When depth $\mathsf{S}_{K,M} > 0$, any closed stratum $S \in \mathsf{S}_{K,M}$ is a K-invariant submanifold of M and then it possesses a K-invariant tubular neighborhood $(T, \tau, S, \mathbb{R}^m)$ whose structural group is $O(m)$. Recall that there are the following smooth maps associated with this neighborhood:

+ The *radius map* $\rho\colon T \to [0,1[$ defined fiberwise from the assignation $[x,t] \mapsto t$. Each $t \neq 0$ is a regular value of the ρ. The pre-image $\rho^{-1}(0)$ is S. This map is K-invariant, that is, $\rho(k\cdot z) = \rho(z)$.

+ The *contraction* $H\colon T\times[0,1] \to T$ defined fiberwisely from $([x,t],r) \mapsto [x,rt]$. The restriction $H_t\colon T \to T$ is an embedding for each $t \neq 0$ and $H_0 \equiv \tau$. We shall write $H(z,t) = t\cdot z$. This map is K-invariant, that is, $t\cdot(k\cdot z) = k\cdot(t\cdot z)$.

The hyper-surface $D = \rho^{-1}(1/2)$ is the *tube* of the tubular neighborhood. It is a K-invariant submanifold of T. Notice that the map

$$\nabla\colon D\times[0,1[\longrightarrow T,$$

defined by $\nabla(z,t) = (2t)\cdot z$ is a K-equivariant smooth map, where K acts trivially on the $[0,1[$-factor. Its restriction $\nabla\colon D\times]0,1[\longrightarrow T\backslash S$ is a K-equivariant diffeomorphism.

Denote S_{min} the union of closed (minimal) strata and choose T_{min} a disjoint family of K-invariant tubular neighborhoods of the closed strata. The union of associated tubes is denoted by D_{min}. Notice that the induced map $\nabla_{min}\colon D_{min}\times]0,1[\longrightarrow T_{min}\backslash S_{min}$ is a K-equivariant diffeomorphism.

4.2 Molino's blow up. The Molino' blow up [7] of the foliation $\mathcal{F}$ produces a new foliation $\widehat{\mathcal{F}}$ of the same kind but of smaller depth. We suppose depth $\mathsf{S}_{K,M} > 0$. The *blow up* of M is the compact manifold

$$\widehat{M} = \Big\{\Big(D_{min}\times]-1,1[\Big) \bigsqcup \Big((M\backslash S_{min})\times\{-1,1\}\Big)\Big\}\Big/\sim,$$

where $(z,t)\sim(\nabla_{min}(z,|t|), t/|t|)$, and the map $\mathcal{L}\colon \widehat{M} \longrightarrow M$ defined by

$$\mathcal{L}(v) = \begin{cases} \nabla_{min}(z,|t|) & \text{if } v = (z,t) \in D_{min}\times]-1,1[\\ z & \text{if } v = (z,j) \in (M\backslash S_{min})\times\{-1,1\}. \end{cases}$$

Notice that $\mathcal{L}$ is a continuous map whose restriction $\mathcal{L}\colon \widehat{M}\backslash\mathcal{L}^{-1}(S_{min}) \to M\backslash S_{min}$ is a K-equivariant smooth trivial 2-covering.

[8] For notions related with compact Lie group actions, we refer the reader to [1].

Since the map ∇_{min} is K-equivariant then Φ induces the action $\widehat{\Phi}\colon K \times \widehat{M} \longrightarrow \widehat{M}$ by saying that the blow-up $\mathcal{L}$ is K-equivariant. The open submanifolds $\mathcal{L}^{-1}(T_{min})$ and $\mathcal{L}^{-1}(T_{min} \backslash S_{min})$ are clearly K-diffeomorphic to $D_{min}\times]-1,1[$ and $D_{min} \times (]-1,0[\cup]0,1[)$ respectively.

The restriction $\widehat{\Phi}\colon G\times\widehat{M} \longrightarrow \widehat{M}$ is an isometric action with K as a tamer group. The induced Killing foliation is $\widehat{\mathcal{F}}$. Foliations $\mathcal{F}$ and $\widehat{\mathcal{F}}$ are related by $\mathcal{L}$ which is a foliated map. Moreover, if S is a not minimal stratum of $\mathsf{S}_{K,M}$ then there exists an unique stratum $S' \in \mathsf{S}_{K,\widehat{M}}$ such that $\mathcal{L}^{-1}(S) \subset S'$. The family $\{S' \,/\, S \in \mathsf{S}_{K,M}\}$ covers $\widehat{M}$ and verifies the relationship: $S_1 \prec S_2 \Leftrightarrow S'_1 \prec S'_2$. We conclude the important property

$$\text{depth } \mathsf{S}_{K,\widehat{M}} < \text{depth } \mathsf{S}_{K,M}. \tag{9}$$

4.3 Finiteness of a tubular neighborhood. We suppose depth $\mathsf{S}_{K,M} > 0$. Consider a closed stratum $S \in \mathsf{S}_{K,M}$. Take $(T,\tau,S,\mathbb{R}^m)$ a K-invariant tubular neighborhood. We fix a base point $x \in S$. The isotropy subgroup K_x acts orthogonally on the fiber $\mathbb{R}^m = \tau^{-1}(x)$. So, the induced action $\Lambda_x\colon G_x \times \mathbb{R}^m \to \mathbb{R}^m$ is an isometric action, it gives the Killing foliation $\mathcal{N}$ on $\mathbb{R}^m$.

Proposition 4.3.1 *If the BIC of $(\mathbb{R}^m,\mathcal{N})$ is finite dimensional then the BIC of $(T,\mathcal{F})$ is also finite dimensional.*

Proof. We proceed in two steps.

(a) *$K_y = K_x$ for each $y \in S$.*

The canonical projection $\pi\colon S \to S/K$ is an homogeneous bundle with fiber K/K_x. For any open subset $V \subset S/K$ the pull back $\tau^{-1}\pi^{-1}(V)$ is a K-invariant subset of T, then we can apply the Mayer-Vietoris technics to this kind of subsets (cf. 2.5).

Since the manifold S/K is a compact one then we can find a finite good covering $\{U_i \,/\, i \in I\}$ of it (cf. [2]). An inductive argument on the cardinality of I reduces the proof of the Lemma to the case where $T = \tau^{-1}\pi^{-1}(V)$, where V is a contractible open subset of S/K.

Here, the manifold T is K-equivalently diffeomorphic to $V \times \left(K\times_{K_x}\mathbb{R}^m\right)$, where K does not act on the first factor. So, the natural retraction of V to a point gives a K-equivariant retraction of T to the twisted product $K\times_{K_x}\mathbb{R}^m$. Now the result comes directly from 3.5(b) since (K,G,K_x) is a trio.

(b) *General case*.

The stratum S is K-equivariantly diffeomorphic to the twisted product $K\times_{N(K_x)}F$ where $N(K_x)$ is the normalizer of K_x on K and $F = S^{K_x}$. So, the tubular neighborhood T is K-equivariantly diffeomorphic to the twisted product $K\times_{N(H)}N$ where N is the manifold $\tau^{-1}(F)$. The previous case gives that the BIC of $(N,\mathcal{F}_N)$ is finite dimensional. Now the result comes directly from 3.5(b) since $(K,G,N(K_x))$ is a trio. ♣

The main result of this work is the following

Theorem 4.4 *The BIC of the foliation determined by an isometric action on a compact manifold is finite dimensional.*

Proof. Let $\mathcal{F}$ be a Killing foliation defined on a compact manifold M induced by an isometric action $\Phi\colon G \times M \to M$ where G is a Lie group. Without loss of generality we can suppose that the Lie group G is a connected one (cf. Lemma 1.1.1). We fix a tamer group K. We know that G is normal in K and the quotient group K/G is commutative (cf. Proposition 1.1.2).

Let us consider the following statement

$$\mathfrak{A}(U,\mathcal{F}) = \text{“The BIC } \boldsymbol{H}^*_{\overline{p}}(U/\mathcal{F}) \text{ is finite dimensional for each perversity } \overline{p}\text{,”}$$

where $U \subset M$ is a K-invariant submanifold. We prove $\mathfrak{A}(M,\mathcal{F})$ by induction on $\dim M$. The result is clear when $\dim M = 0$. We suppose $\mathfrak{A}(W,\mathcal{F})$ for any K-invariant compact submanifold W of M with $\dim W < \dim M$ and we prove $\mathfrak{A}(M,\mathcal{F})$. We proceed in several steps.

First step: 0-depth. Let us suppose depth $\mathsf{S}_{K,M} = 0$. Since $G \triangleleft K$ and K_x is conjugated to K_y then G_x is conjugated to G_y, $\forall x, y \in M$. We get that the foliation $\mathcal{F}$ is a (regular) riemannian foliation (cf. [7]). Its BIC is just the basic cohomology (cf. 2.3). Then $\mathfrak{A}(M,\mathcal{F})$ comes from [4].

Second step: Inside M. Let us suppose depth $\mathsf{S}_{K,M} > 0$. The family $\{M\backslash S_{min}, T_{min}\}$ is a basic covering of M and the we get the exact sequence (cf. 2.5)

$$0 \to \Omega^*_{\overline{p}}(M/\mathcal{F}) \to \Omega^*_{\overline{p}}((M\backslash S_{min})/\mathcal{F}) \oplus \Omega^*_{\overline{p}}(T_{min}/\mathcal{F}) \to \Omega^*_{\overline{p}}((T_{min}\backslash S_{min})/\mathcal{F}) \to 0.$$

The Five Lemma gives

$$\mathfrak{A}(T_{min}\backslash S_{min},\mathcal{F}),\ \ \mathfrak{A}(T_{min},\mathcal{F}) \text{ and } \mathfrak{A}(M\backslash S_{min},\mathcal{F}) \Longrightarrow \mathfrak{A}(M,\mathcal{F}).$$

Since $T_{min}\backslash S_{min}$ is K-diffeomorphic to $D_{min}\times]0,1[$ (cf. (cf. 4.1)) then $\mathfrak{A}(D_{min},\mathcal{F}) \Longrightarrow \mathfrak{A}(T_{min}\backslash S_{min},\mathcal{F})$. The inequality $\dim D_{min} < \dim M$ gives

$$\mathfrak{A}(T_{min},\mathcal{F}) \text{ and } \mathfrak{A}(M\backslash S_{min},\mathcal{F}) \Longrightarrow \mathfrak{A}(M,\mathcal{F}).$$

In order to prove $\mathfrak{A}(T_{min},\mathcal{F})$ it suffices to prove $\mathfrak{A}(T,\mathcal{F})$ where $(T,\tau,S,\mathbb{R}^m)$ a K-invariant tubular neighborhood of closed stratum S of $\mathsf{S}_{K,M}$. Following Proposition 4.3.1 we have

$$\mathfrak{A}(\mathbb{R}^m,\mathcal{N}) \Longrightarrow \mathfrak{A}(T,\mathcal{F}) \Longrightarrow \mathfrak{A}(T_{min},\mathcal{F}).$$

Consider the orthogonal decomposition $\mathbb{R}^m = \mathbb{R}^{m_1}\times\mathbb{R}^{m_2}$, where $\mathbb{R}^{m_1} = (\mathbb{R}^m)^{G_x}$. The only fixed point of the restriction $\Lambda_x\colon G_x\times\mathbb{R}^{m_2}\to\mathbb{R}^{m_2}$ is the origin. So, there exists a Killing foliation[9] $\mathcal{G}$ on the sphere $\mathbb{S}^{m_2-1}$ with $(\mathbb{R}^{m_1}\times\mathbb{R}^{m_2},\mathcal{F}) = (\mathbb{R}^{m_1}\times c\mathbb{S}^{m_2-1}, \mathcal{I}\times c\mathcal{G})$. Propositions 2.6 and 2.7 give:

$$\mathfrak{A}(\mathbb{S}^{m_2-1},\mathcal{G}) \Longrightarrow \mathfrak{A}(\mathbb{R}^{m_1}\times c\mathbb{S}^{m_2-1}, \mathcal{I}\times c\mathcal{G}) \Longrightarrow \mathfrak{A}(\mathbb{R}^m,\mathcal{N}).$$

Finally, since $\dim\mathbb{S}^{m_2-1} < m \le \dim T \le \dim M$ we have

$$\mathfrak{A}(M\backslash S_{min},\mathcal{F}) \Longrightarrow \mathfrak{A}(M,\mathcal{F}). \tag{10}$$

Third step: Blow-up. Let us suppose depth $\mathsf{S}_{K,M} > 0$. The family $\left\{\mathcal{L}^{-1}(M\backslash S_{min}), \mathcal{L}^{-1}(T_{min})\right\}$ is a basic covering of $\widehat{M}$ and the we get the exact sequence (cf. 2.5)

$$0 \to \Omega^*_{\overline{p}}\left(\widehat{M}/\widehat{\mathcal{F}}\right) \to \Omega^*_{\overline{p}}\left(\mathcal{L}^{-1}(M\backslash S_{min})/\widehat{\mathcal{F}}\right) \oplus \Omega^*_{\overline{p}}\left(\mathcal{L}^{-1}(T_{min})/\widehat{\mathcal{F}}\right) \to \Omega^*_{\overline{p}}\left(\mathcal{L}^{-1}(T_{min}\backslash S_{min})/\widehat{\mathcal{F}}\right) \to 0.$$

Following 4.2 we have that

- $\mathcal{L}^{-1}(M\backslash S_{min})$ is K-diffeomorphic to two copies of $M\backslash S_{min}$,
- $\mathcal{L}^{-1}(T_{min})$ is K-diffeomorphic to $D_{min}\times]-1,1[$,
- $\mathcal{L}^{-1}(T_{min}\backslash S_{min})$ is K-diffeomorphic to $D_{min}\times(]-1,0[\cup]0,1[)$.

[9] It is given by the orthogonal action $\Lambda_x\colon G_x\times\mathbb{S}^{m_2-1}\to\mathbb{S}^{m_2-1}$.

Now, the Five Lemma gives

$$\mathfrak{A}(D_{min},\widehat{\mathcal{F}}) \text{ and } \mathfrak{A}\left(\widehat{M},\widehat{\mathcal{F}}\right) \Longrightarrow \mathfrak{A}(M\backslash S_{min},\mathcal{F}).$$

But, the inequality $\dim D_{min} < \dim M$ gives

$$\mathfrak{A}\left(\widehat{M},\widehat{\mathcal{F}}\right) \Longrightarrow \mathfrak{A}(M\backslash S_{min},\mathcal{F}). \tag{11}$$

Forth step: Final blow-up. When depth $\mathsf{S}_{K,M} = 0$ we get $\mathfrak{A}(M,\mathcal{F})$ from the First step. Let us suppose depth $\mathsf{S}_{K,M} > 0$. From (10) and (11) we get

$$\mathfrak{A}\left(\widehat{M},\widehat{\mathcal{F}}\right) \Longrightarrow \mathfrak{A}(M,\mathcal{F}).$$

with depth $\mathsf{S}_{K,\widetilde{M}} <$ depth $\mathsf{S}_{K,M}$ (cf. (9)). By iterating this procedure we get

$$\mathfrak{A}\left(\widetilde{M},\widetilde{\mathcal{F}}\right) = \mathfrak{A}\left(\widehat{\cdots}\,\widehat{\mathcal{M}},\widehat{\cdots}\,\widehat{\mathcal{F}}\right) \Longrightarrow \cdots \Longrightarrow \mathfrak{A}\left(\widehat{M},\widehat{\mathcal{F}}\right) \Longrightarrow \mathfrak{A}(M,\mathcal{F}),$$

with depth $\mathsf{S}_{K,\widetilde{M}} = 0$. We finish the proof by applying again the First Step. ♣
